Five suggestions on how to prevent human-made disasters

Monitoring, enforcing environmental protection laws, public health safety measures and heavy sanctions must be put in place to avoid harm posed by Industries in every sector

Public awareness program should be encouraged

Policies should be taken by individual sectors to ensure safe storage of hazardous chemicals

There should be adequate communication and cooperation between key stakeholders.

Hazardous sites should be far from residential areas

- Question 8
- Supervised learning, that means having a full set of labeled data while training an algorithm. Fully labeled means that each example in the training dataset is tagged with the answer the algorithm should come up with on its own
- Whereas, in unsupervised learning, a deep learning model is handed a dataset without explicit instructions on what to do with it. The training dataset is a collection of examples without a specific desired outcome or correct answer. The neural network then attempts to automatically find structure in the data by extracting useful features and analyzing its structure. It does not have a perfectly labeled dataset, hence
- The difference between supervised and unsupervised learning is that supervised learning uses labeled datasets, and unsupervised learning does not. Supervised learning requires more human preparation at the beginning of the process due to the need for proper labeling. The labeling is used as a guide to determine if its pattern recognition is accurate or not.
- Unsupervised learning models work independently on unlabeled datasets with little human supervision. Because unsupervised learning does not require a hypothesis to identify patterns, it removes hypothesis bias.
- For supervised and unsupervised models of Disaster prevention the Dimensional Model, Monte-carlo Simulations can be used to determine weather patterns, disaster forecasting so that effective prevention measures can be planned.
